

# Vascular Model Repository

## Specifications Document

### 0058\_H\_PULMFON\_PAT

Legacy Name: 0076\_0001

Model added: 27 Dec 2021

<b>Species</b>	Human
<b>Anatomy</b>	Pulmonary Fontan
<b>Disease</b>	Pulmonary Atresia
<b>Procedure</b>	Fontan

# Clinical Significance and Background

## Pulmonary Fontan

The pulmonary arteries are the blood vessels responsible for transporting deoxygenated blood to the lungs to perform respiration. A normal pulmonary anatomy involves the main pulmonary artery (MPA) trunk leaving the right ventricle of the heart which then branches off into the left and right pulmonary arteries which then continue to fractally branch towards the lungs. However, after the Fontan procedure (an open-heart surgery done on babies with congenital heart defects) the anatomy of the pulmonary system is slightly modified. The main pulmonary artery trunk is not present. Instead, the superior vena cava (SVC) and inferior vena cava (IVC) are directly connected to the left and right pulmonary arteries in a 4-way intersection configuration. This is done so that deoxygenated blood coming from the upper body (through the SVC) and deoxygenated blood coming from the lower body (through the IVC) flow directly to the lungs without passing through the heart to allow for the heart to focus solely on pumping oxygenated blood from the lungs to the rest of the body.

## Pulmonary Atresia

Pulmonary atresia is a birth defect of the pulmonary valve, which is the valve that controls blood flow from the right ventricle (lower right chamber of the heart) to the main pulmonary artery (the blood vessel that carries blood from the heart to the lungs). Pulmonary atresia is when this valve did not form at all, and no blood can go from the right ventricle of the heart out to the lungs.

In pulmonary atresia, since blood cannot directly flow from the right ventricle of the heart out to the pulmonary artery, blood must use other routes to bypass the unformed pulmonary valve. The foramen ovale, a natural opening between the right and left upper chambers of the heart during pregnancy that usually closes after the baby is born, often remains open to allow blood flow to the lungs.

## Fontan

The Fontan procedure is a type of open-heart surgery. Children who need this surgery usually have it when they are 18 - 36 months old. The Fontan procedure is done for children who are born with heart problems like hypoplastic left heart syndrome (HLHS), tricuspid atresia, and double outlet right ventricle, and depending on the heart problem, children may need the Norwood procedure and Glenn procedure before the Fontan

surgery.

After the Fontan procedure, the blood from the lower body goes directly to the lungs. The blood with high oxygen goes into the heart. This way the single ventricle only pumps blood to the body and only pumps blood with high oxygen to the body. There is no more mixing of oxygen-rich blood and oxygen-poor blood.

During the Fontan procedure, the surgeon first disconnects the inferior vena cava (IVC) from the heart and connects it to the pulmonary artery using a conduit (tube). Then, the surgeon makes a small hole between the conduit and the right atrium. This hole (or fenestration) lets some blood still flow back to the heart. It prevents too much blood from flowing to the lungs right away, so they have time to adjust. Doctors can close the fenestration later by doing a cardiac catheterization procedure.

## Clinical Data

### General Patient Data

Age (yrs)	26
Sex	Female

### Specific Patient Data

BSA (m <sup>2</sup> )	0.68
CI (L/min/m <sup>2</sup> )	3.8
P IVC MP cath	15
P SVC MP cath	15
P LPA MP cath	14
P RPA MP cath	14
P aorta SP cath	140
P aorta DP cath	95
P aorta MP cath	108

## Notes

Paper patient "B". See [paper](#) for more details. See below for information on the image data.

**Image Modality:** MR

**Image Type:** VTI

**Image Source:** TLAB

**Image Manufacturer:** GE MEDICAL SYSTEMS

## Publications

See the following publications which include the featured model for more details:
